Chapter 1 Device Overview MC9S12XD-Family

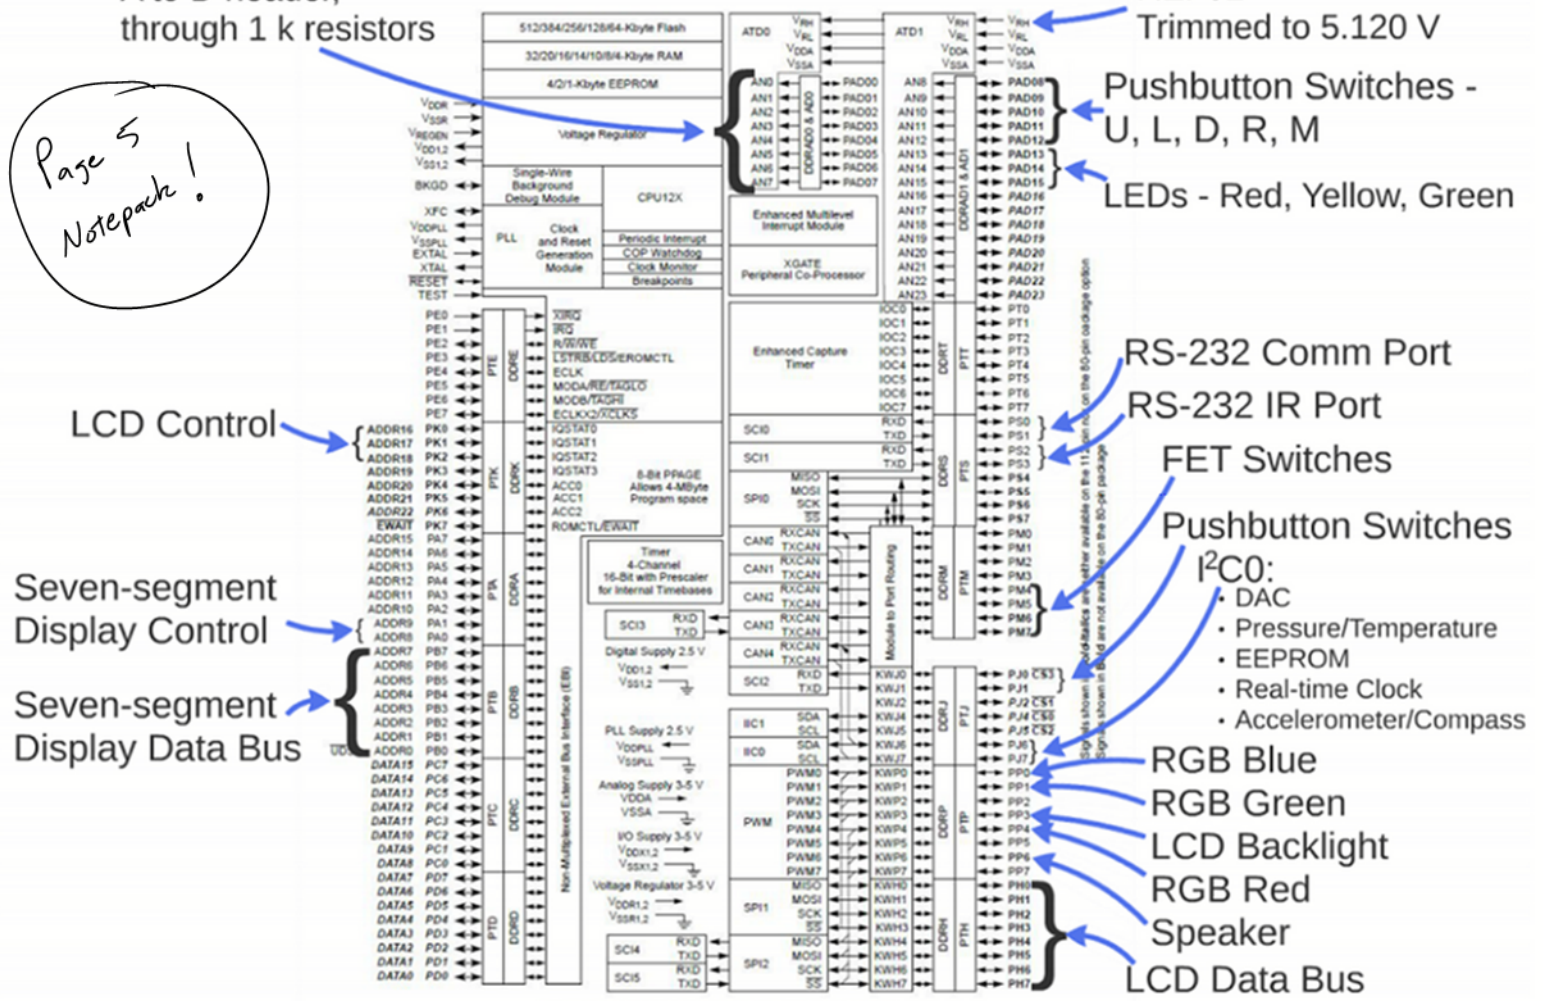

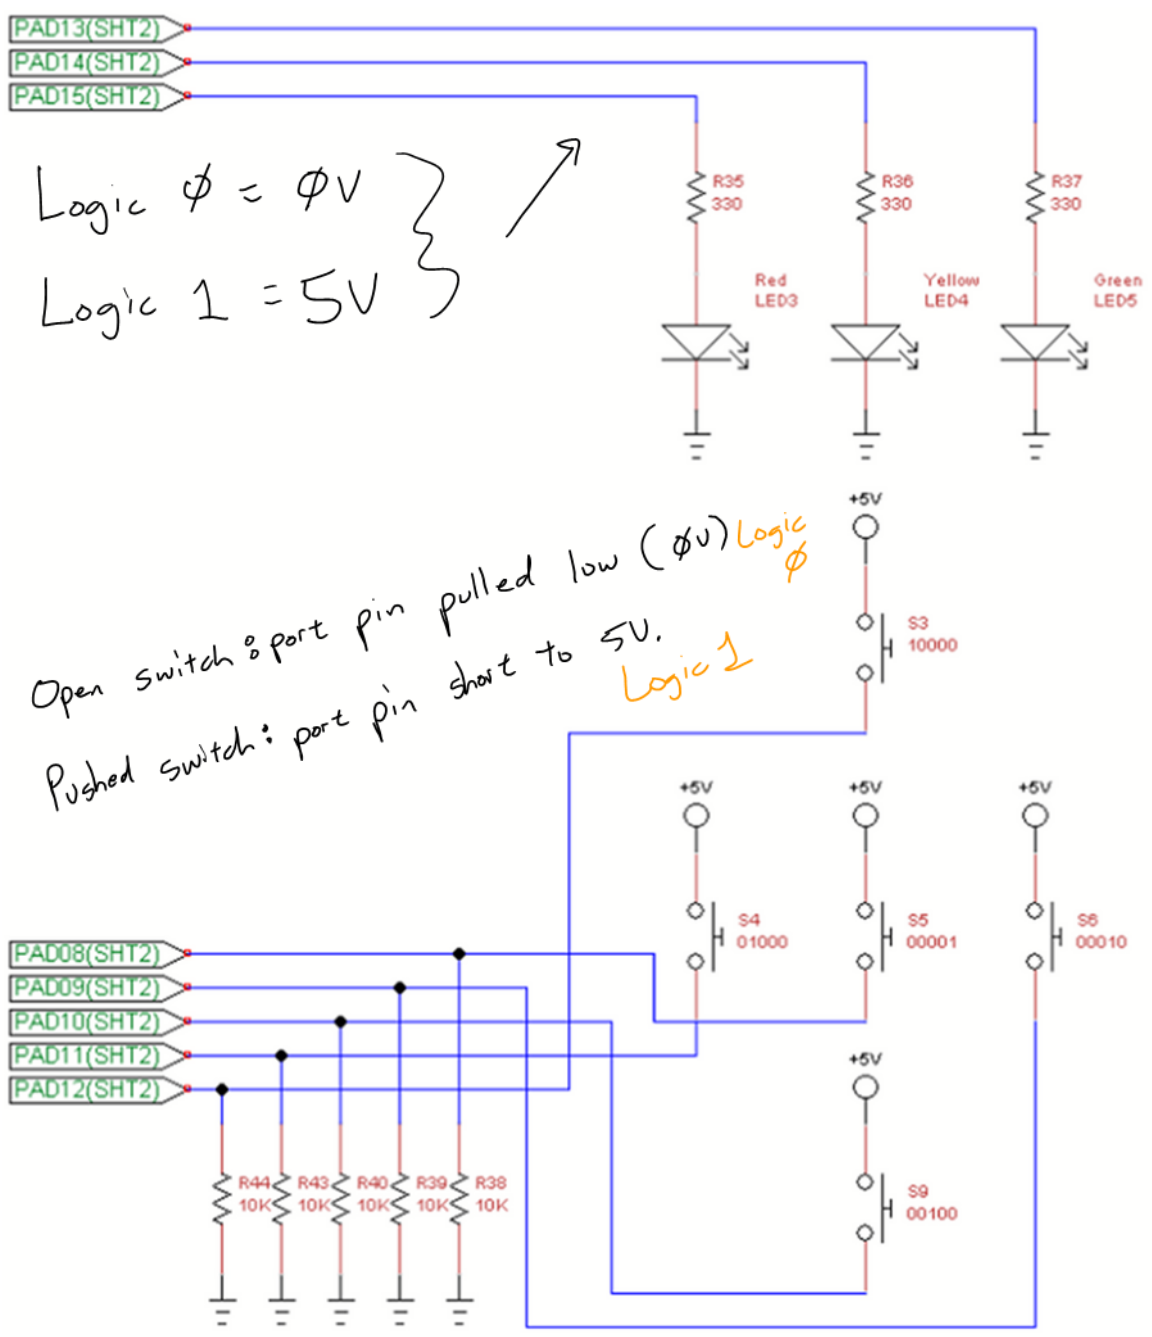

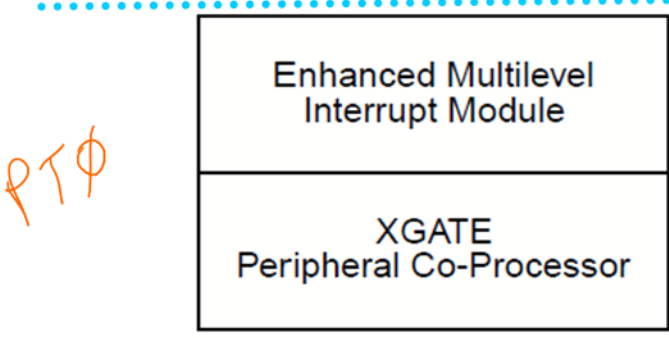

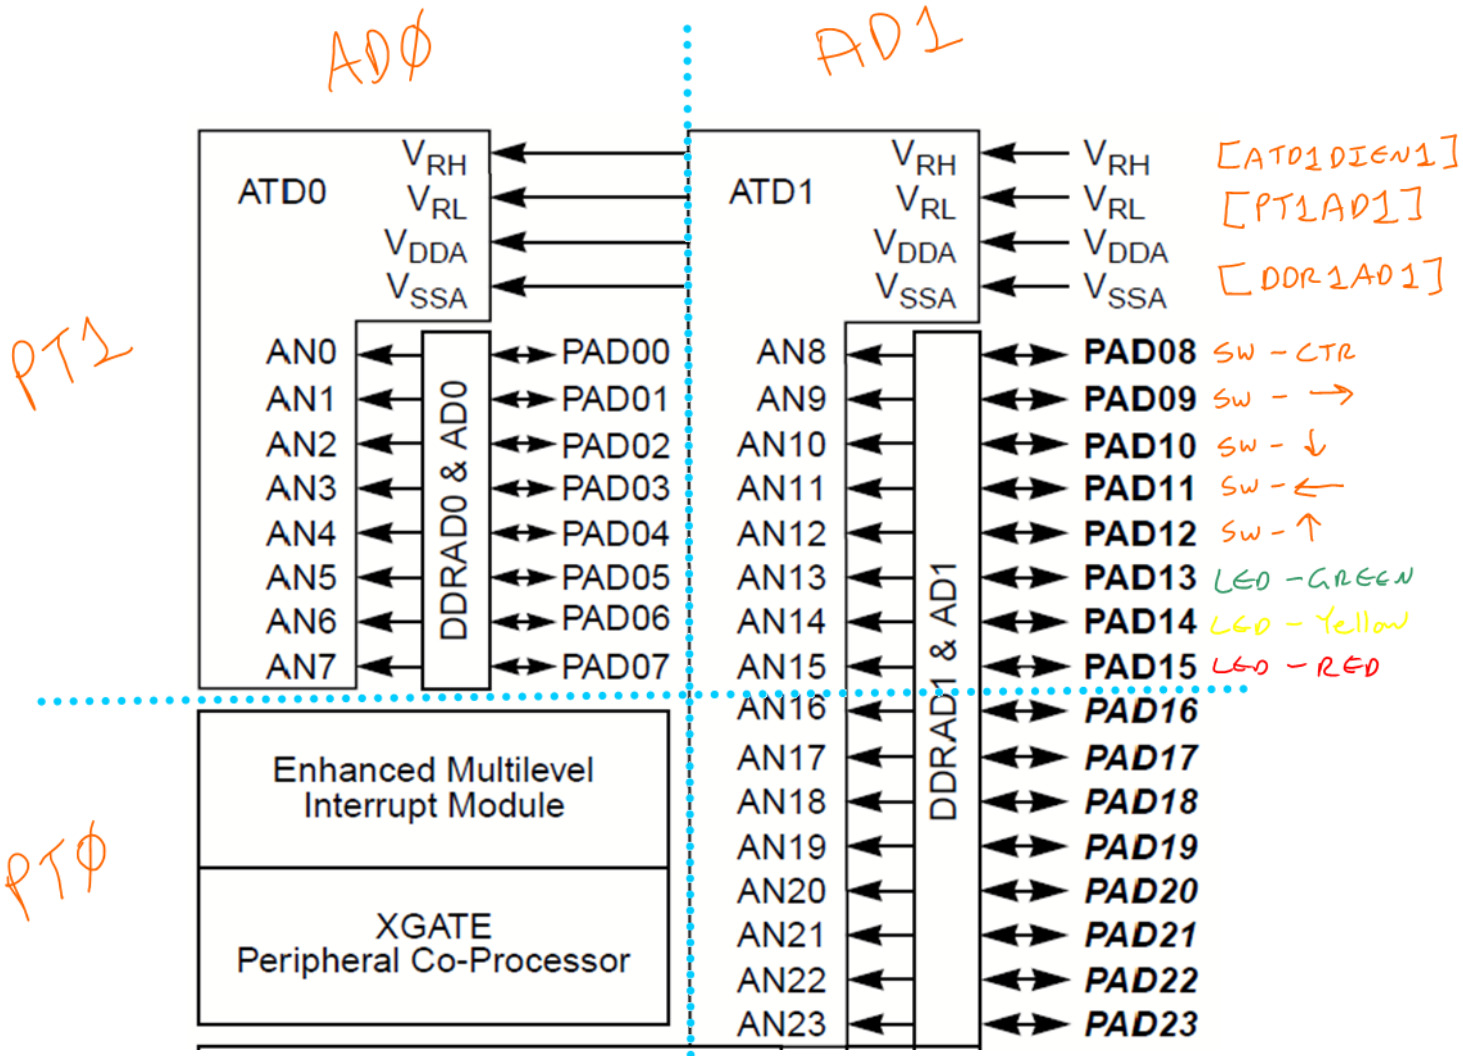

Figure 1-1. MC9S12XD-Family Block Diagram

Logic $\phi = \phi V$
Logic 1 = 5V

Open switch: port pin pulled low (ϕ) Logic ϕ
Pushed switch: port pin short to 5V. Logic 1

When we initialize the port, we want it to come up in a known state. This is important for outputs.

We don't want that X-Ray gun starting up when it should not.

The port is buffered, so if we write to it, those values will be expressed when the port pin Δ 's to an output.

We want the LEDs to be outputs, and the switches to be inputs: 22.3.2.69 of "Big Pink"

22.3.2.69 Port AD1 Data Direction Register 1 (DDR1AD1)

Figure 22-71. Port AD1 Data Direction Register 1 (DDR1AD1)

| Field | Description |
|----------------------|--|
| 7-0 DDR1AD1[15:8] | <p>Data Direction Port AD1 Register 1</p> <p>0 Associated pin is configured as input.</p> <p>1 Associated pin is configured as output.</p> <p><i>3! So... 1s for LEDs 0s for SWITCHES</i></p> <p>Note: Due to internal synchronization circuits, it can take up to 2 bus clock cycles until the correct value is read on PTAD11 register, when changing the DDR1AD1 register.</p> <p>Note: To use the digital input function on port AD1 the ATD1 digital input enable register (ATD1DIEN1) has to be set to logic level "1".</p> |

OUR STEPS THEN, TO INIT THE SWITCHES AND LEDs:

- ① Write ϕ s to the port (PT1AD1) for the LEDs to make sure they will be off when we activate outputs.
- ② Write ϕ s/1s to DDR1AD1 to make switches inputs/LEDs outputs.
- ③ Enable digital inputs for the switches (ATD1DIEN1).

When these three steps are complete, we can read the switches and turn on/off the LEDs through PT1AD1.

Let's Try...
